- Principle:

- The Penman-Monteith Equation is differentiated in time and decomposed into five main terms; the first two are atmospheric forcings and the remainder are feedbacks:

$$\frac{1}{c_0} \frac{dLE}{dt} = \left\{ \frac{dq_{Sat}}{dT} \left[(1-\alpha) \frac{dS_{\downarrow}}{dt} + \frac{dL_{\downarrow}}{dt} \right] \right\} + \left\{ \left(H \frac{d^2 q_{Sat}}{dT^2} + \frac{\rho c_p}{r_a} \frac{dq_{Sat}}{dT} \right) adv_{\theta} - \frac{\rho c_p}{r_a} adv_q \right\}$$

$$+ \left\{ \left(H \frac{d^2 q_{Sat}}{dT^2} + \frac{\rho c_p}{r_a} \frac{dq_{Sat}}{dT} \right) \left(\frac{H}{\rho c_p h} + \frac{w_e \Delta \theta}{h} \right) - \frac{\rho c_p}{r_a} \left(\frac{LE}{\rho \lambda_v h} + \frac{w_e \Delta q}{h} \right) \right\}$$

$$- \left\{ \left(\frac{\rho c_p}{r_a^2} (q_{Sat} - q) - LE \frac{c_p r_s}{\lambda_v r_a^2} \right) \frac{dr_a}{dt} \right\} - \left\{ \frac{dq_{Sat}}{dT} \frac{dL_{\uparrow}}{dt} + \frac{dq_{Sat}}{dT} \frac{dG}{dt} + LE \frac{c_p}{\lambda_v r_a} \frac{dr_s}{dt} \right\}$$

$$c_0 = 1 / \left[\frac{dq_{Sat}}{dT} + \frac{c_p}{\lambda_v} \left(1 + \frac{r_s}{r_a} \right) \right]$$

See references for all symbol definitions.

- The five terms, each in {}, are (1) radiative tendency forcings; (2) boundary layer advective forcings; (3) boundary layer feedbacks (surface sensible warming, entrainment warming, surface moistening, and entrainment drying); (4) surface layer feedback; (5) land surface feedbacks (surface OLR, ground heat flux, and stomatal resistance).
- Data needs:
 - Models often have all needed terms for diagnosis.
- Observational data sources:
 - Many terms (e.g., r_s , w_e) are nearly impossible to measure in the field.
- Caveats:
 - Well suited to SCM or LEM output, possibly GCM or regional model output as well.
 - Specific terms may be estimated from default model output, but perhaps not all.
 - If LE is not calculated in the model using a Penman-Monteith formulation, there will be discrepancy in the diagnostics.
